## Abstract

Metamaterials, artificial materials with engineered subwavelength nanostructures, can possess optical functions unavailable for natural materials. Tuning these functions is highly desired in many applications. Although various methods have been reported, they often have limited performance in switching speed, energy consumption, and modulation depth. In this talk, I will present our recent results on a new control method, coherent control, which allows for switching at THz frequency and single-photon level with near-unity modulation. The method uses coherent light beams to create standing waves with various electromagnetic field configurations. We have demonstrated in both theory and experiment several possible applications including optical computation [1,2], multipole spectroscopy [3], and polarization-sensitive detection [4].
