Abstract

The coupling between electrons, spins and phonons is vital for understanding the properties of correlated materials and the interesting phenomena they exhibit, such as high temperature superconductivity. However, many correlated materials are antiferromagnetic, which poses significant challenges for how to observe such coupling.

In this talk I will discuss two techniques that our group has been using in order to understand these interactions. The first technique is non-linear optics, which we use to understand the coupling between electrons, phonons and spins in the insulating antiferromagnet Cr_2O_3 [1]. The second is time-resolved resonant inelastic X-ray scattering which enables us to measure the dynamics of spin waves on the nanoscale in Sr_2IrO_4 [2].

Finally, if time permits, I will discuss our recent attempts to perform resonant X-ray spectroscopy on the nanoscale by exploiting X-ray holography. This enables us to image nanoscale phase separation in strongly correlated materials.
